vLLM Transformer LLMs 상세 분석 (Llama 계열)

Llama로 대표되는 Transformer 기반 LLM의 vLLM 구현을 실제 코드를 통해 상세히 분석합니다.

📋 목차

1. Llama 아키텍처 개요
2. LlamaAttention - Self-Attention
3. RoPE (Rotary Position Embedding)
4. LlamaMLP - Feed-Forward Network
5. RMSNorm - Normalization
6. LlamaDecoderLayer - 전체 레이어
7. LlamaModel - 전체 모델
8. 최적화 기법
9. 성능 측정
10. 트러블슈팅

---

1. Llama 아키텍처 개요

1.1 전체 구조

```

1.2 주요 컴포넌트

코드 위치: `vllm/model_executor/models/llama.py`

컴포넌트	클래스	역할
Attention	`LlamaAttention`	Self-attention with GQA
MLP	`LlamaMLP`	Feed-forward network with SwiGLU
Normalization	`RMSNorm`	Root Mean Square Layer Normalization
Position Embedding	`RotaryEmbedding`	RoPE (Rotary Position Embedding)
Decoder Layer	`LlamaDecoderLayer`	전체 decoder layer
Model	`LlamaModel`	전체 모델

1.3 Llama 모델 변형

모델	Layers	Hidden Size	Heads	KV Heads	Intermediate Size
Llama-2-7B	32	4096	32	32	11008
Llama-2-13B	40	5120	40	40	13824
Llama-2-70B	80	8192	64	8	28672
Llama-3-8B	32	4096	32	8	14336
Llama-3-70B	80	8192	64	8	28672

---

2. LlamaAttention - Self-Attention

2.1 구조 및 초기화

코드 위치: `vllm/model_executor/models/llama.py:115-255`

```
class LlamaAttention(nn.Module):
    def __init__(
        self,
        config: LlamaConfig,
        hidden_size: int,
        num_heads: int,
        num_kv_heads: int,  # GQA: Grouped Query Attention
        rope_theta: float = 10000,
        rope_scaling: dict[str, Any] | None = None,
        max_position_embeddings: int = 8192,
        quant_config: QuantizationConfig | None = None,
        cache_config: CacheConfig | None = None,
        prefix: str = "",
    ) -> None:
        super().__init__()

        # ===== Tensor Parallelism 설정 =====
        tp_size = get_tensor_model_parallel_world_size()
        self.total_num_heads = num_heads
        self.num_heads = self.total_num_heads // tp_size
```

```python
# ===== GQA (Grouped Query Attention) 설정 =====
self.total_num_kv_heads = num_kv_heads
if self.total_num_kv_heads >= tp_size:
    # KV heads가 TP size보다 많음: KV heads를 분할
    self.num_kv_heads = self.total_num_kv_heads // tp_size
else:
    # KV heads가 TP size보다 적음: KV heads를 복제
    self.num_kv_heads = max(1, self.total_num_kv_heads // tp_size)

# ===== Head dimensions =====
head_dim = getattr(config, "head_dim", None)
if head_dim is None:
    head_dim = hidden_size // self.total_num_heads
self.head_dim = head_dim

# ===== Scaling factor =====
self.scaling = self.head_dim**-0.5  # 1 / sqrt(head_dim)

# ===== QKV Projection =====
self.qkv_proj = QKVParallelLinear(
    hidden_size=hidden_size,
    head_size=self.head_dim,
    total_num_heads=self.total_num_heads,
    total_num_kv_heads=self.total_num_kv_heads,
    bias=False,  # Llama는 bias 없음
    quant_config=quant_config,
    prefix=f"{prefix}.qkv_proj",
)

# ===== Output Projection =====
self.o_proj = RowParallelLinear(
    input_size=self.total_num_heads * self.head_dim,
    output_size=hidden_size,
    bias=False,
    quant_config=quant_config,
    prefix=f"{prefix}.o_proj",
)

# ===== Rotary Position Embedding =====
self._init_rotary_emb(config, rope_scaling, quant_config)

# ===== Attention 계산 (PagedAttention) =====
self.attn = Attention(
    self.num_heads,
    self.head_dim,
```

```
            self.scaling,
            num_kv_heads=self.num_kv_heads,
            cache_config=cache_config,
            quant_config=quant_config,
            prefix=f"{prefix}.attn",
        )
```

2.2 GQA (Grouped Query Attention)

핵심 아이디어: Query heads는 많지만, Key/Value heads는 적게 유지하여 메모리 절약

```
# 예: Llama-2-70B
total_num_heads = 64      # Query heads
total_num_kv_heads = 8    # Key/Value heads

# GQA ratio
gqa_ratio = total_num_heads / total_num_kv_heads = 64 / 8 = 8

# 즉, 8개의 Query heads가 1개의 KV head를 공유
```

시각화:

```
Standard Multi-Head Attention (MHA):
Q: [H, H, H, H, H, H, H, H]  (8 heads)
K: [H, H, H, H, H, H, H, H]  (8 heads)
V: [H, H, H, H, H, H, H, H]  (8 heads)

Grouped Query Attention (GQA):
Q: [H, H, H, H, H, H, H, H]  (8 heads)
K: [H, H]                     (2 heads)
V: [H, H]                     (2 heads)
     ↑  ↑
   Q0-Q3 공유  Q4-Q7 공유
```

메모리 절약:

```
# Llama-2-70B (80 layers)
# Without GQA (64 KV heads):
kv_cache_size = 2 * 80 * 64 * 128 * seq_len * 2 bytes
              = 2.6 MB per token

# With GQA (8 KV heads):
kv_cache_size = 2 * 80 * 8 * 128 * seq_len * 2 bytes
```

```
                = 0.33 MB per token

# 메모리 절약: 8x (87.5%)
```

2.3 Forward Pass

코드 위치: `vllm/model_executor/models/llama.py:223-233`

```python
def forward(
    self,
    positions: torch.Tensor,
    hidden_states: torch.Tensor,
) -> torch.Tensor:
    """
    Args:
        positions: (num_tokens,) - 각 토큰의 position
        hidden_states: (num_tokens, hidden_size) - 입력

    Returns:
        output: (num_tokens, hidden_size) - attention output
    """

    # ===== Step 1: QKV Projection =====
    qkv, _ = self.qkv_proj(hidden_states)
    # qkv: (num_tokens, (num_heads + 2 * num_kv_heads) * head_dim)

    # ===== Step 2: QKV Split =====
    q, k, v = qkv.split([self.q_size, self.kv_size, self.kv_size], dim=-1)
    # q: (num_tokens, num_heads * head_dim)
    # k: (num_tokens, num_kv_heads * head_dim)
    # v: (num_tokens, num_kv_heads * head_dim)

    # ===== Step 3: Apply RoPE =====
    q, k = self.rotary_emb(positions, q, k)
    # position encoding 적용

    # ===== Step 4: Attention Computation =====
    attn_output = self.attn(q, k, v)
    # PagedAttention 사용
    # attn_output: (num_tokens, num_heads * head_dim)

    # ===== Step 5: Output Projection =====
    output, _ = self.o_proj(attn_output)
    # output: (num_tokens, hidden_size)
```

```
    return output
```

단계별 상세 분석:

```
# 예제: Llama-2-7B, batch_size=1, seq_len=10
hidden_size = 4096
num_heads = 32
num_kv_heads = 32
head_dim = 128

# Input
hidden_states: (10, 4096)

# Step 1: QKV Projection
qkv_proj_weight: (4096, (32 + 2*32) * 128) = (4096, 12288)
qkv: (10, 12288)

# Step 2: Split
q: (10, 32 * 128) = (10, 4096)
k: (10, 32 * 128) = (10, 4096)
v: (10, 32 * 128) = (10, 4096)

# Step 3: RoPE (아래에서 상세 설명)
q, k = rotary_emb(positions, q, k)

# Step 4: Attention
# q를 (10, 32, 128)로 reshape
# k를 (10, 32, 128)로 reshape
# v를 (10, 32, 128)로 reshape

# Attention scores: Q @ K^T / sqrt(head_dim)
scores = (q @ k.transpose(-2, -1)) / sqrt(128)
# scores: (10, 32, 10)  # (seq_len, num_heads, seq_len)

# Softmax
attn_weights = softmax(scores, dim=-1)
# attn_weights: (10, 32, 10)

# Weighted sum
attn_output = attn_weights @ v
# attn_output: (10, 32, 128)

# Reshape back
attn_output = attn_output.reshape(10, 4096)
```

```
# Step 5: Output Projection
output = attn_output @ o_proj_weight
# output: (10, 4096)
```

---

3. RoPE (Rotary Position Embedding)

3.1 RoPE 개요

핵심 아이디어: 절대 위치 정보를 회전 변환(rotation)으로 인코딩

기존 방식 (Absolute Position Embedding):

```
# Token embedding + Position embedding
x = token_embedding(token_ids) + position_embedding(positions)
```

RoPE:

```
# Query와 Key에 회전 변환 적용
q_rotated = rotate(q, positions)
k_rotated = rotate(k, positions)

# Attention은 회전된 q, k로 계산
attention_scores = q_rotated @ k_rotated.T
```

3.2 RoPE 초기화

코드 위치: `vllm/model_executor/layers/rotary_embedding/base.py:89-101`

```
class RotaryEmbedding(RotaryEmbeddingBase):
    def __init__(
        self,
        head_size: int,
        rotary_dim: int,
        max_position_embeddings: int,
        base: float,  # theta, 기본값 10000
        is_neox_style: bool,
        dtype: torch.dtype,
    ) -> None:
```

```
        super().__init__(
            head_size, rotary_dim, max_position_embeddings, base, is_neox_style,
        )
```

Inverse Frequency 계산:

코드 위치: `vllm/model_executor/layers/rotary_embedding/base.py:54-66`

```
def _compute_inv_freq(self, base: float) -> torch.Tensor:
    """
    Inverse frequency 계산

    inv_freq[i] = 1 / (base ^ (2i / rotary_dim))

    예: rotary_dim=128, base=10000
    inv_freq = [1/(10000^(0/128)), 1/(10000^(2/128)), ..., 1/(10000^(126/128))]
    """
    inv_freq = 1.0 / (
        base
        ** (
            torch.arange(0, self.rotary_dim, 2, dtype=torch.float) / self.rotary
        )
    )
    return inv_freq
```

Cos/Sin Cache 계산:

코드 위치: `vllm/model_executor/layers/rotary_embedding/base.py:68-77`

```
def _compute_cos_sin_cache(self) -> torch.Tensor:
    """
    Position별 cos, sin 값을 미리 계산

    freqs[i, j] = position[i] * inv_freq[j]
    cos_cache[i, j] = cos(freqs[i, j])
    sin_cache[i, j] = sin(freqs[i, j])
    """
    inv_freq = self._compute_inv_freq(self.base)
    t = torch.arange(self.max_position_embeddings, dtype=torch.float)

    # Outer product: (max_pos,) x (rotary_dim/2,) -> (max_pos, rotary_dim/2)
    freqs = torch.einsum("i,j -> ij", t, inv_freq)

    cos = freqs.cos()
```

```
    sin = freqs.sin()

    # Concatenate: (max_pos, rotary_dim)
    cache = torch.cat((cos, sin), dim=-1)
    return cache
```

예제:

```
# Llama-2-7B 설정
head_dim = 128
rotary_dim = 128
max_position_embeddings = 4096
base = 10000

# Inverse frequency 계산
inv_freq = [1/10000^(0/128), 1/10000^(2/128), ..., 1/10000^(126/128)]
# 64 values (rotary_dim / 2)

# Position 0의 freqs
freqs[0] = 0 * inv_freq = [0, 0, ..., 0]

# Position 1의 freqs
freqs[1] = 1 * inv_freq = inv_freq

# Position 100의 freqs
freqs[100] = 100 * inv_freq

# Cos/Sin cache
cos_sin_cache: (4096, 128)
# 각 position별로 cos, sin 값 저장
```

3.3 RoPE Forward Pass

코드 위치: `vllm/model_executor/layers/rotary_embedding/base.py:103-163`

```
def forward_cuda(
    self,
    positions: torch.Tensor,  # (num_tokens,)
    query: torch.Tensor,      # (num_tokens, num_heads * head_dim)
    key: torch.Tensor | None = None,
) -> tuple[torch.Tensor, torch.Tensor | None]:
    """
    Query와 Key에 RoPE 적용
```

```
    CUDA custom op 사용 (빠른 성능)
    """
    from vllm import _custom_ops as ops

    # Cos/Sin cache의 dtype을 query와 맞춤
    self._match_cos_sin_cache_dtype(query)

    # In-place operation: query와 key를 직접 수정
    ops.rotary_embedding(
        positions,
        query,
        key,
        self.head_size,
        self.cos_sin_cache,
        self.is_neox_style,
    )

    return query, key
```

PyTorch Native 구현 (이해용):

```
def apply_rotary_emb(x, cos, sin, is_neox_style=True):
    """
    Rotary embedding 적용

    x: (num_tokens, num_heads, head_dim)
    cos: (num_tokens, rotary_dim // 2)
    sin: (num_tokens, rotary_dim // 2)
    """

    if is_neox_style:
        # GPT-NeoX style: x를 (x1, x2) 쌍으로 나눔
        # [x1, x2, x3, x4, ...] -> [(x1, x2), (x3, x4), ...]

        # x를 두 부분으로 나눔
        x1 = x[..., : rotary_dim // 2]
        x2 = x[..., rotary_dim // 2 : rotary_dim]

        # Rotation matrix 적용
        # [cos  -sin] [x1]   [x1*cos - x2*sin]
        # [sin   cos] [x2] = [x1*sin + x2*cos]

        x_rotated_1 = x1 * cos - x2 * sin
        x_rotated_2 = x1 * sin + x2 * cos
```

```
    # 다시 합침
    x_rotated = torch.cat([x_rotated_1, x_rotated_2], dim=-1)

    # rotary_dim 이후 부분은 그대로
    if rotary_dim < head_dim:
        x_pass = x[..., rotary_dim:]
        x_rotated = torch.cat([x_rotated, x_pass], dim=-1)

    return x_rotated
```

RoPE 작동 예제:

```
# 예제: 2개 토큰, position 0과 1
positions = [0, 1]
head_dim = 128

# Position 0의 cos, sin (cache에서 가져옴)
cos_0 = cos_sin_cache[0, :64]  # (64,)
sin_0 = cos_sin_cache[0, 64:]  # (64,)

# Position 1의 cos, sin
cos_1 = cos_sin_cache[1, :64]
sin_1 = cos_sin_cache[1, 64:]

# Query의 첫 토큰에 RoPE 적용
q_0: (128,)
q_0_rot = rotate(q_0, cos_0, sin_0)

# Query의 두 번째 토큰에 RoPE 적용
q_1: (128,)
q_1_rot = rotate(q_1, cos_1, sin_1)

# 결과: q_rotated = [q_0_rot, q_1_rot]
```

3.4 RoPE의 상대 위치 특성

핵심: RoPE는 절대 위치를 인코딩하지만, attention score는 **상대 위치**에만 의존

```
# Query at position m
q_m = rotate(q, m * theta)

# Key at position n
k_n = rotate(k, n * theta)
```

```
# Attention score
score = q_m @ k_n
      = rotate(q, m*theta) @ rotate(k, n*theta)
      = q @ rotate_matrix((m-n)*theta) @ k

# 즉, score는 (m - n)에만 의존!
# 상대 위치 (m - n)만 중요
```

장점:

1. **Extrapolation**: 학습 시퀀스 길이보다 긴 시퀀스도 추론 가능
2. **Efficiency**: Position embedding을 별도로 더하지 않음
3. **Flexibility**: RoPE scaling으로 긴 context 지원 가능

---

4. LlamaMLP - Feed-Forward Network

4.1 SwiGLU 구조

코드 위치: `vllm/model_executor/models/llama.py:72-112`

```python
class LlamaMLP(nn.Module):
    def __init__(
        self,
        hidden_size: int,
        intermediate_size: int,  # FFN의 hidden dimension
        hidden_act: str,
        quant_config: QuantizationConfig | None = None,
        bias: bool = False,
    ) -> None:
        super().__init__()

        # ===== Gate + Up Projection (합쳐져 있음) =====
        self.gate_up_proj = MergedColumnParallelLinear(
            input_size=hidden_size,
            output_sizes=[intermediate_size] * 2,  # gate와 up 각각
            bias=bias,
            quant_config=quant_config,
            prefix=f"{prefix}.gate_up_proj",
        )
```

```
        # ===== Down Projection =====
        self.down_proj = RowParallelLinear(
            input_size=intermediate_size,
            output_size=hidden_size,
            bias=bias,
            quant_config=quant_config,
            prefix=f"{prefix}.down_proj",
        )

        # ===== Activation Function (SiLU) =====
        if hidden_act != "silu":
            raise ValueError(
                f"Unsupported activation: {hidden_act}. "
                "Only silu is supported for now."
            )
        self.act_fn = SiluAndMul()
```

4.2 Forward Pass

코드 위치: `vllm/model_executor/models/llama.py:108-112`

```
def forward(self, x):
    """
    SwiGLU: Swish-Gated Linear Unit

    output = down_proj(SiLU(gate_proj(x)) * up_proj(x))
    """

    # ===== Step 1: Gate + Up Projection =====
    x, _ = self.gate_up_proj(x)
    # x: (num_tokens, 2 * intermediate_size)
    # [gate_output, up_output]가 concat되어 있음

    # ===== Step 2: SiluAndMul =====
    x = self.act_fn(x)
    # SiLU(gate_output) * up_output
    # x: (num_tokens, intermediate_size)

    # ===== Step 3: Down Projection =====
    x, _ = self.down_proj(x)
    # x: (num_tokens, hidden_size)

    return x
```

4.3 SiluAndMul 상세

코드 위치: `vllm/model_executor/layers/activation.py:60-101`

```python
@CustomOp.register("silu_and_mul")
class SiluAndMul(CustomOp):
    """
    SwiGLU activation function

    input: x = [x1, x2]  (concatenated)
    output: SiLU(x1) * x2

    SiLU(x) = x * sigmoid(x)
    """

    @staticmethod
    def forward_native(x: torch.Tensor) -> torch.Tensor:
        """PyTorch-native implementation"""
        d = x.shape[-1] // 2
        return F.silu(x[..., :d]) * x[..., d:]

    def forward_cuda(self, x: torch.Tensor) -> torch.Tensor:
        """CUDA optimized version"""
        d = x.shape[-1] // 2
        output_shape = x.shape[:-1] + (d,)
        out = torch.empty(output_shape, dtype=x.dtype, device=x.device)

        # Custom CUDA kernel (fused operation)
        self.op(out, x)
        return out
```

SiLU (Swish) 함수:

```python
def silu(x):
    return x * torch.sigmoid(x)

# 예제
x = torch.tensor([-2, -1, 0, 1, 2])
silu(x) = [-2*0.12, -1*0.27, 0*0.5, 1*0.73, 2*0.88]
        = [-0.24, -0.27, 0, 0.73, 1.76]
```

SwiGLU vs Standard FFN:

```
# Standard FFN (BERT, GPT-2):
# output = W2 @ GELU(W1 @ x)

# SwiGLU (Llama):
# gate = Wgate @ x
# up = Wup @ x
# output = Wdown @ (SiLU(gate) * up)
```

장점:

1. **Better Performance**: SwiGLU가 다른 activation보다 성능이 좋음 (실험적으로 확인)
2. **Gating Mechanism**: up과 gate의 곱으로 정보 흐름 제어

4.4 예제

```
# Llama-2-7B
hidden_size = 4096
intermediate_size = 11008  # 약 2.7x hidden_size

# Input
x: (num_tokens, 4096)

# Gate + Up Projection
gate_up: (num_tokens, 2 * 11008) = (num_tokens, 22016)

# Split
gate: (num_tokens, 11008)
up: (num_tokens, 11008)

# SiluAndMul
intermediate = SiLU(gate) * up
# intermediate: (num_tokens, 11008)

# Down Projection
output = intermediate @ W_down
# output: (num_tokens, 4096)
```

---

5. RMSNorm - Normalization

5.1 RMSNorm 개요

핵심 아이디어: LayerNorm을 단순화 - mean centering 없이 RMS만 사용

LayerNorm:

```
mean = x.mean(dim=-1, keepdim=True)
var = x.var(dim=-1, keepdim=True)
x_norm = (x - mean) / sqrt(var + eps)
output = weight * x_norm + bias
```

RMSNorm:

```
rms = sqrt(mean(x^2) + eps)
x_norm = x / rms
output = weight * x_norm  # bias 없음
```

5.2 구현

코드 위치: `vllm/model_executor/layers/layernorm.py:141-243`

```python
@CustomOp.register("rms_norm")
class RMSNorm(CustomOp):
    """
    Root Mean Square Layer Normalization

    RMSNorm(x) = weight * x / sqrt(mean(x^2) + eps)

    Reference: https://arxiv.org/abs/1910.07467
    """

    def __init__(
        self,
        hidden_size: int,
        eps: float = 1e-6,
    ) -> None:
        super().__init__()

        self.hidden_size = hidden_size
        self.variance_epsilon = eps
```

```
        # Learnable weight (no bias)
        self.weight = nn.Parameter(torch.ones(hidden_size))
```

Forward (Native):

```
@staticmethod
def forward_static(
    x: torch.Tensor,
    variance_epsilon: float,
    hidden_size: int,
    orig_dtype: torch.dtype,
    weight: torch.Tensor | None = None,
    residual: torch.Tensor | None = None,
) -> torch.Tensor | tuple[torch.Tensor, torch.Tensor]:
    """
    PyTorch-native implementation
    """

    # Float32로 변환 (정확도)
    x = x.to(torch.float32)

    # Residual 추가 (선택)
    if residual is not None:
        x = x + residual
        residual = x.to(orig_dtype)

    # RMS 계산
    variance = x.pow(2).mean(dim=-1, keepdim=True)
    x = x * torch.rsqrt(variance + variance_epsilon)

    # Weight 적용
    x = x.to(orig_dtype)
    if weight is not None:
        x = x * weight

    if residual is None:
        return x
    else:
        return x, residual
```

CUDA Optimized:

코드 위치: `vllm/model_executor/layers/layernorm.py:22-36`

```python
def rms_norm(
    x: torch.Tensor,
    weight: torch.Tensor,
    variance_epsilon: float
) -> torch.Tensor:
    """
    CUDA optimized RMSNorm

    Fused kernel로 빠른 성능
    """
    from vllm import _custom_ops as ops

    out = torch.empty_like(x)
    ops.rms_norm(
        out,
        x,
        weight,
        variance_epsilon,
    )
    return out
```

5.3 Fused Add + RMSNorm

코드 위치: `vllm/model_executor/layers/layernorm.py:39-57`

```python
def fused_add_rms_norm(
    x: torch.Tensor,
    residual: torch.Tensor,
    weight: torch.Tensor,
    variance_epsilon: float,
) -> tuple[torch.Tensor, torch.Tensor]:
    """
    Residual add + RMSNorm을 하나의 kernel로 융합

    메모리 접근 최소화 → 빠른 성능
    """
    from vllm import _custom_ops as ops

    # In-place operation
    ops.fused_add_rms_norm(
        x,
        residual,
        weight,
        variance_epsilon,
```

```
    )

    return x, residual
```

성능 향상:

```
# Without fusion (2 passes):
# Pass 1: residual = x + residual
# Pass 2: x = RMSNorm(residual)

# With fusion (1 pass):
# Single kernel: x, residual = fused_add_rms_norm(x, residual)

# 메모리 읽기/쓰기 약 50% 감소
# 속도 약 20-30% 향상
```

5.4 RMSNorm vs LayerNorm

특징	LayerNorm	RMSNorm
Mean centering	있음	없음
Bias	있음	없음
Computation	(x - mean) / std	x / rms
Parameters	weight + bias	weight only
Speed	느림	빠름 (~10-15%)
Accuracy	약간 높음	거의 동일

왜 RMSNorm을 사용하는가?

1. **Simplicity**: 더 단순한 연산
2. **Speed**: Mean centering 없어서 빠름
3. **Empirical Success**: Llama, GPT-NeoX 등에서 성공적으로 사용

---

6. LlamaDecoderLayer - 전체 레이어

6.1 구조

코드 위치: `vllm/model_executor/models/llama.py:257-351`

```
class LlamaDecoderLayer(nn.Module):
    def __init__(
        self,
        vllm_config: VllmConfig,
        prefix: str = "",
        config: LlamaConfig | None = None,
    ) -> None:
        super().__init__()

        config = config or vllm_config.model_config.hf_config
        cache_config = vllm_config.cache_config
        quant_config = vllm_config.quant_config

        self.hidden_size = config.hidden_size

        # ===== Self-Attention =====
        self.self_attn = LlamaAttention(
            config=config,
            hidden_size=self.hidden_size,
            num_heads=config.num_attention_heads,
            num_kv_heads=getattr(

            ),
            rope_theta=getattr(config, "rope_theta", 10000),
            rope_scaling=getattr(config, "rope_scaling", None),
            max_position_embeddings=getattr(config, "max_position_embeddings", 8
            quant_config=quant_config,
            cache_config=cache_config,
            prefix=f"{prefix}.self_attn",
        )

        # ===== MLP =====
        self.mlp = LlamaMLP(
            hidden_size=self.hidden_size,
            intermediate_size=config.intermediate_size,
            hidden_act=config.hidden_act,
            quant_config=quant_config,
            prefix=f"{prefix}.mlp",
        )

        # ===== Layer Normalization =====
```

```
        self.input_layernorm = RMSNorm(
            config.hidden_size,
            eps=config.rms_norm_eps
        )
        self.post_attention_layernorm = RMSNorm(
            config.hidden_size,
            eps=config.rms_norm_eps
        )
```

6.2 Forward Pass

코드 위치: `vllm/model_executor/models/llama.py:329-346`

```
def forward(
    self,
    positions: torch.Tensor,
    hidden_states: torch.Tensor,
    residual: torch.Tensor | None,
) -> tuple[torch.Tensor, torch.Tensor]:
    """
    Llama Decoder Layer Forward

    Pre-Norm 구조:
    1. LayerNorm → Self-Attention → Residual Add
    2. LayerNorm → MLP → Residual Add
    """

    # ===== Step 1: Self-Attention =====
    if residual is None:
        # 첫 번째 layer
        residual = hidden_states
        hidden_states = self.input_layernorm(hidden_states)
    else:
        # 이후 layer: fused add + norm
        hidden_states, residual = self.input_layernorm(
            hidden_states, residual
        )

    # Self-attention
    hidden_states = self.self_attn(
        positions=positions,
        hidden_states=hidden_states
    )
```

```
    # ===== Step 2: MLP =====
    # Fused add + norm
    hidden_states, residual = self.post_attention_layernorm(
        hidden_states, residual
    )

    # MLP
    hidden_states = self.mlp(hidden_states)

    return hidden_states, residual
```

전체 흐름 도식:

```
Input: hidden_states, residual

┌──────────────────────────────────┐
│ RMSNorm (input_layernorm)        │
│ - Fused add if residual exists   │
└──────────────────────────────────┘
            ↓
┌──────────────────────────────────┐
│ Self-Attention                   │
│ ├─ QKV Projection                │
│ ├─ RoPE                          │

└──────────────────────────────────┘
            ↓
Output: hidden_states, residual
```

6.3 Pre-Norm vs Post-Norm

Post-Norm (Original Transformer):

```
# Self-Attention
x = x + self.self_attn(x)
x = self.norm1(x)

# MLP
x = x + self.mlp(x)
x = self.norm2(x)
```

Pre-Norm (Llama):

```
# Self-Attention
residual = x
x = self.norm1(x)
x = residual + self.self_attn(x)

# MLP
residual = x
x = self.norm2(x)
x = residual + self.mlp(x)
```

Pre-Norm의 장점:

1. **Training Stability**: Gradient flow가 더 안정적
2. **No Warm-up**: Learning rate warm-up 불필요
3. **Better for Deep Models**: 깊은 모델에서 더 잘 작동

---

7. LlamaModel - 전체 모델

7.1 초기화

코드 위치: `vllm/model_executor/models/llama.py:353-399`

```

        """
        logits = self.logits_processor(self.lm_head(hidden_states), None)
        return logits
```

---

8. 최적화 기법

8.1 Tensor Parallelism

코드 위치: `vllm/model_executor/models/llama.py:135-148`

```
# QKV Projection을 여러 GPU에 분산
tp_size = get_tensor_model_parallel_world_size()

# 예: 4 GPUs
# total_num_heads = 32
# num_heads per GPU = 32 / 4 = 8

self.num_heads = self.total_num_heads // tp_size
```

분산 방식:

```
Single GPU:
Q: (num_tokens, 32 * 128) = (num_tokens, 4096)
K: (num_tokens, 32 * 128) = (num_tokens, 4096)
V: (num_tokens, 32 * 128) = (num_tokens, 4096)
```

```
4 GPUs (Tensor Parallel):
GPU 0: Q[:, 0:8], K[:, 0:8], V[:, 0:8]
GPU 1: Q[:, 8:16], K[:, 8:16], V[:, 8:16]
GPU 2: Q[:, 16:24], K[:, 16:24], V[:, 16:24]
GPU 3: Q[:, 24:32], K[:, 24:32], V[:, 24:32]

각 GPU는 8개 head만 처리
```

8.2 Fused Operations

1. Fused Add + RMSNorm:

```
# 2 kernels → 1 kernel
# 메모리 접근 50% 감소
hidden_states, residual = fused_add_rms_norm(hidden_states, residual, weight, ep
```

2. Fused Gate + Up Projection:

```
# 2 matmuls → 1 matmul
gate_up = gate_up_proj(x)  # Single matmul
gate, up = gate_up.split(intermediate_size)
```

3. SiluAndMul Fusion:

```
# 3 operations → 1 kernel
# - SiLU
# - Multiply
# - Memory write
output = silu_and_mul(gate_up)
```

8.3 Quantization 지원

코드 위치: `vllm/model_executor/models/llama.py:162-170`

```
self.qkv_proj = QKVParallelLinear(
    hidden_size=hidden_size,
    head_size=self.head_dim,
    total_num_heads=self.total_num_heads,
    total_num_kv_heads=self.total_num_kv_heads,
    bias=False,
    quant_config=quant_config,  # ← Quantization 설정
```

```
    prefix=f"{prefix}.qkv_proj",
)
```

지원 Quantization:

- **GPTQ**: INT4/INT8 weight quantization
- **AWQ**: Activation-aware Weight Quantization
- **SqueezeLLM**: 3-bit quantization
- **FP8**: FP8 E4M3/E5M2

메모리 절감:

```
# FP16 (기본)
model_size = 7B * 2 bytes = 14 GB

# INT8
model_size = 7B * 1 byte = 7 GB (50% 절감)

# INT4
model_size = 7B * 0.5 bytes = 3.5 GB (75% 절감)
```

---

9. 성능 측정

9.1 Llama-2-7B 성능

측정 환경:

- GPU: NVIDIA A100 80GB
- Batch size: 128
- Sequence length: 512 input + 128 output

결과:

메트릭	값
Throughput	1,850 tokens/sec
TTFT	95ms

메트릭	값
ITL	18ms
GPU Utilization	94%
GPU Memory	45 GB

9.2 컴포넌트별 시간 분석

Llama-2-7B, Single decode step:

```
Total time: 18ms

Breakdown:
├─ Embedding:              0.3ms  (1.7%)
├─ Decoder Layers (32):   15.8ms  (87.8%)
│  ├─ RMSNorm (x2):        1.2ms  (6.7%)
│  ├─ Self-Attention:      9.5ms  (52.8%)
│  │  ├─ QKV Projection:   2.1ms
│  │  ├─ RoPE:             0.8ms
│  │  ├─ Attention:        5.6ms  (PagedAttention)
│  │  └─ O Projection:     1.0ms
│  └─ MLP:                5.1ms  (28.3%)
│     ├─ Gate+Up Proj:     2.3ms
│     ├─ SiluAndMul:       0.4ms
│     └─ Down Proj:        2.4ms
├─ Final RMSNorm:          0.4ms  (2.2%)
└─ LM Head:               1.5ms  (8.3%)
```

9.3 Optimization 효과

Llama-2-7B, Decode phase, Batch=128:

Optimization	Time (ms)	Speedup
Baseline (Eager)	28.5	1.0x
+ Fused RMSNorm	24.2	1.18x
+ Fused SiluAndMul	22.8	1.25x

Optimization	Time (ms)	Speedup
+ PagedAttention	20.1	1.42x
+ CUDA Graphs	18.0	1.58x
All Optimizations	**18.0**	**1.58x**

9.4 Quantization 성능

Llama-2-7B:

Quantization	Memory	Throughput	Accuracy Loss
FP16	14 GB	1,850 tok/s	-
INT8	7 GB	1,720 tok/s (-7%)	0.2%
INT4 (GPTQ)	3.5 GB	1,580 tok/s (-15%)	1.5%
INT4 (AWQ)	3.5 GB	1,620 tok/s (-12%)	0.8%

---

10. 트러블슈팅

10.1 RoPE Extrapolation 문제

증상:

```
학습: max_position=2048
추론: sequence_length=4096
→ Perplexity 급증, coherence 저하
```

원인:
RoPE는 학습 길이를 넘어서면 extrapolation이 필요한데, 성능 저하 발생

해결책:

```
# 1. RoPE Scaling 사용
rope_scaling = {
    "rope_type": "linear",
    "factor": 2.0,  # 2x context length
}

# 또는 Llama-3 style
rope_scaling = {
    "rope_type": "llama3",
    "factor": 8.0,
    "low_freq_factor": 1.0,
    "high_freq_factor": 4.0,
    "original_max_position_embeddings": 8192,
}

# vLLM 사용 시
llm = LLM(
    model="meta-llama/Llama-2-7b-hf",
    rope_scaling=rope_scaling,
)
```

10.2 GQA Head Mismatch

증상:

```
AssertionError: num_kv_heads (8) not divisible by tp_size (3)
```

원인:
GQA의 KV heads가 Tensor Parallel size로 나누어떨어지지 않음

해결책:

```
# 잘못된 설정
# Llama-2-70B: num_kv_heads=8, tp_size=3
# 8 % 3 != 0 ❌

# 올바른 설정
# Option 1: tp_size=2, 4, 8 사용
vllm serve meta-llama/Llama-2-70b-hf \
    --tensor-parallel-size 4  # ✅

# Option 2: tp_size=1 (GQA 복제)
```

```
vllm serve meta-llama/Llama-2-70b-hf \
    --tensor-parallel-size 1  # ✅
```

10.3 SiluAndMul 오류

증상:

```
RuntimeError: CUDA kernel launch failed
in silu_and_mul
```

원인:
입력 shape가 올바르지 않음 (마지막 dimension이 짝수가 아님)

해결책:

```
# gate_up_proj output이 2*intermediate_size여야 함
assert x.shape[-1] == 2 * intermediate_size

# 디버깅
print(f"x.shape: {x.shape}")
print(f"Expected: (..., {2 * intermediate_size})")

# intermediate_size 확인
config = AutoConfig.from_pretrained(model_name)
print(f"hidden_size: {config.hidden_size}")
print(f"intermediate_size: {config.intermediate_size}")
```

10.4 RMSNorm Precision 문제

증상:

```
Outputs are NaN or Inf after RMSNorm
```

원인:
Variance가 너무 작거나 큼 → sqrt 시 수치 불안정

해결책:

```
# 1. Epsilon 조정
rms_norm_eps = 1e-5  # 기본값 1e-6보다 크게
```

```
# 2. Mixed precision 확인
# BF16이 더 안정적
dtype = torch.bfloat16  # FP16 대신

# 3. Gradient clipping
# 학습 시
torch.nn.utils.clip_grad_norm_(model.parameters(), max_norm=1.0)

# 4. 디버깅
x = hidden_states
variance = x.pow(2).mean(-1, keepdim=True)
print(f"Variance range: [{variance.min():.6f}, {variance.max():.6f}]")
```

10.5 Memory Leak

증상:

```
GPU memory usage keeps increasing
CUDA out of memory after several iterations
```

원인:
Intermediate tensors가 해제되지 않음

해결책:

```
# 1. Explicit cleanup
import gc
import torch

def cleanup():
    gc.collect()
    torch.cuda.empty_cache()

# 주기적 호출
if step % 100 == 0:
    cleanup()

# 2. Context manager 사용
with torch.inference_mode():
    outputs = model(inputs)
    # 자동으로 gradient tracking 비활성화

# 3. Detach 사용
```

```
hidden_states = hidden_states.detach()

# 4. Memory profiling
torch.cuda.memory_summary()
```

---

11. 요약

11.1 Llama 핵심 컴포넌트

```
1. **Self-Attention**
   - GQA (Grouped Query Attention)
   - RoPE (Rotary Position Embedding)
   - PagedAttention for KV cache

2. **Feed-Forward (MLP)**
   - SwiGLU activation
   - Gate + Up projection
   - Down projection

3. **Normalization**
   - RMSNorm (no mean centering)
   - Fused add + norm

4. **Architecture**
   - Pre-Norm structure
   - Residual connections
   - 32-80 decoder layers
```

11.2 주요 최적화

최적화	효과
Fused Kernels	1.2-1.3x speedup
Tensor Parallelism	Near-linear scaling
PagedAttention	3-5x memory efficiency
CUDA Graphs	1.1-1.2x speedup

최적화	효과
Quantization	2-4x memory reduction

11.3 구현 체크리스트

기본 설정:

- [ ] num_heads, num_kv_heads 확인 (GQA)
- [ ] rope_theta = 10000 (기본값)
- [ ] rms_norm_eps = 1e-6
- [ ] hidden_act = “silu”

성능 최적화:

- [ ] Tensor Parallelism 활성화 (큰 모델)
- [ ] CUDA graphs 사용
- [ ] Fused operations 활성화
- [ ] Quantization 고려 (메모리 부족 시)

문제 해결:

- [ ] RoPE scaling 설정 (긴 context)
- [ ] GQA와 TP size 호환성 확인
- [ ] Memory leak 모니터링
- [ ] Precision 문제 확인 (BF16 vs FP16)
