Omni Octane 아키텍처 심층 분석

목차

1. Omni Octane 개요
2. 핵심 아키텍처
3. evmengine 모듈 분석
4. ABCI 2.0 통합
5. Engine API 구현
6. Optimistic Payload Building
7. Event Processing 시스템
8. 코드 분석
9. 성능 최적화
10. Cosmos SDK vs Octane 비교

---

1. Omni Octane 개요

1.1 Octane이란?

Octane은 Omni Network가 개발한 **모듈형 EVM 프레임워크**입니다.

> 출처: `omni/octane/README.md` (실제 레포지토리)

```
Octane is a modular framework for the EVM. Developers can use it to run:
- any EVM execution client that implements the Engine API
- any consensus client that implements ABCI 2.0
```

1.2 주요 특징

특징	설명
Modularity	Engine API 구현체 교체 가능 (Geth, Reth, Erigon 등)
ABCI 2.0	CometBFT와 완전 통합
Optimistic Building	Block proposer를 예측하여 사전 빌드
EVM Extensions	Cosmos SDK 모듈과 EVM 간 브릿지 (Staking, Slashing 등)

1.3 아키텍처 다이어그램

2. 핵심 아키텍처

2.1 컴포넌트 구조

실제 코드 기반 (출처: `omni/octane/evmengine/keeper/keeper.go`)

```go
// octane/evmengine/keeper/keeper.go (lines 29-54)
type Keeper struct {
    cdc                     codec.BinaryCodec
    storeService            store.KVStoreService
    headTable               ExecutionHeadTable      // EVM 블록 헤드 추적
    withdrawalTable         WithdrawalTable          // Withdrawal 큐
    engineCl                ethclient.EngineClient  // Engine API 클라이언트
    txConfig                client.TxConfig
    voteProvider            types.VoteExtensionProvider
    eventProcs              []types.EvmEventProcessor // Event 처리기들
    cmtAPI                  comet.API
    addrProvider            types.AddressProvider
    feeRecProvider          types.FeeRecipientProvider
    buildDelay              time.Duration
    buildOptimistic         bool
    maxWithdrawalsPerBlock uint64

    // Optimistic payload building
    mutablePayload struct {
        sync.Mutex
        ID        engine.PayloadID  // Payload 식별자
        Height    uint64
        UpdatedAt time.Time
    }
}
```

주요 필드 분석:

1. `engineCl` : EVM execution client와 통신 (Engine API)
2. `headTable` : 현재 EVM execution head 저장
3. `withdrawalTable` : PoS withdrawal 큐 관리
4. `eventProcs` : EVM 이벤트를 Cosmos SDK로 연결
5. `mutablePayload` : Optimistic building을 위한 사전 빌드 payload

2.2 Keeper 생성

```go
// octane/evmengine/keeper/keeper.go (lines 56-96)
func NewKeeper(
    cdc codec.BinaryCodec,
    storeService store.KVStoreService,
    engineCl ethclient.EngineClient,
    txConfig client.TxConfig,
    addrProvider types.AddressProvider,
    feeRecProvider types.FeeRecipientProvider,
    maxWithdrawalsPerBlock uint64,
    eventProcs ...types.EvmEventProcessor,
) (*Keeper, error) {
    // ORM Database 설정
    schema := &ormv1alpha1.ModuleSchemaDescriptor{
        SchemaFile: []*ormv1alpha1.ModuleSchemaDescriptor_FileEntry{
            {Id: 1, ProtoFileName: File_octane_evmengine_keeper_evmengine_proto.Path()},
        },
    }

    modDB, err := ormdb.NewModuleDB(schema, ormdb.ModuleDBOptions{
        KVStoreService: storeService,
    })
    if err != nil {
        return nil, errors.Wrap(err, "create module db")
    }

    dbStore, err := NewEvmengineStore(modDB)
    if err != nil {
        return nil, errors.Wrap(err, "create evmengine store")
    }

    // Event processors 검증
    if err := verifyProcs(eventProcs); err != nil {
        return nil, err
    }

    return &Keeper{
        cdc:                   cdc,
        storeService:          storeService,
        headTable:             dbStore.ExecutionHeadTable(),
        withdrawalTable:       dbStore.WithdrawalTable(),
        engineCl:              engineCl,
        txConfig:              txConfig,
        addrProvider:          addrProvider,
        feeRecProvider:        feeRecProvider,
        eventProcs:            eventProcs,
        maxWithdrawalsPerBlock: maxWithdrawalsPerBlock,
    }, nil
}
```

3. evmengine 모듈 분석

3.1 디렉터리 구조

```
octane/evmengine/

3.2 핵심 인터페이스

```go
// types/interfaces.go
type EvmEventProcessor interface {
    Name() string
    Address() common.Address
    Deliver(ctx context.Context, blockHash common.Hash, log etypes.Log) error
}

type VoteExtensionProvider interface {
    PrepareVotes(ctx sdk.Context, commit abci.ExtendedCommitInfo, height uint64) ([]sdk.Msg, error)
    VerifyVotes(ctx sdk.Context, commit abci.ExtendedCommitInfo, height uint64) error
}
```

---

4. ABCI 2.0 통합

4.1 PrepareProposal

실제 구현 (출처: `octane/evmengine/keeper/abci.go` lines 32-150)

```go
// PrepareProposal returns a proposal for the next block.
// Note returning an error results proposing an empty block.
func (k *Keeper) PrepareProposal(ctx sdk.Context, req *abci.RequestPrepareProposal) (
    *abci.ResponsePrepareProposal, error,
) {
    // 1. Timeout 설정 (10초)
    const prepareTimeout = time.Second * 10
    timeoutCtx, cancel := context.WithTimeout(ctx.Context(), prepareTimeout)
    defer cancel()
    ctx = ctx.WithContext(timeoutCtx)

    // 2. 트랜잭션이 없는지 확인 (Octane은 CometBFT tx를 사용하지 않음)
    if len(req.Txs) > 0 {
        return nil, errors.New("unexpected transactions in proposal")
    }

    // 3. Height 1은 빈 블록 (gas meter 이슈 회피)
    if req.Height == 1 {
        log.Warn(ctx, "Creating empty initial block due to gas issue", nil)
        return &abci.ResponsePrepareProposal{}, nil
    }

    // 4. Optimistic payload 확인 또는 새로 빌드
    payloadID, height, triggeredAt := k.getOptimisticPayload()
    reqHeight := uint64(req.Height)

    if reqHeight != height {
        // 새 payload 빌드
        err := retryForever(ctx, func(ctx context.Context) (bool, error) {
            fcr, err := k.startBuild(ctx, appHash, req.Time, reqHeight)
            if err != nil {
                log.Warn(ctx, "Preparing proposal failed: build new evm payload (will retry)", err)
                return false, nil // Retry
            }
            // ... 검증 로직
            payloadID = *fcr.PayloadID
            return true, nil
        })
        if err != nil {
            return nil, err
        }
        log.Debug(ctx, "Started non-optimistic payload", "height", req.Height)
    } else {
        log.Debug(ctx, "Using optimistic payload", "height", height, "payload", payloadID)
    }

    // 5. Build delay 대기
    waitTo := triggeredAt.Add(k.buildDelay)
    select {
    case <-ctx.Done():
        return nil, errors.Wrap(ctx.Err(), "context done")
    case <-time.After(time.Until(waitTo)):
    }

    // 6. Payload 가져오기
    var payloadResp *engine.ExecutionPayloadEnvelope
    err = retryForever(ctx, func(ctx context.Context) (bool, error) {
        payloadResp, err = k.engineCl.GetPayloadV3(ctx, payloadID)
        // ... 에러 처리
        return true, nil
    })

    // 7. Vote extensions 수집
    prevHeight := reqHeight - 1
    voteMsgs, err := k.voteProvider.PrepareVotes(ctx, req.LocalLastCommit, prevHeight)

    // 8. Execution payload 메시지 생성
    payloadMsg := &types.MsgExecutionPayload{
        Authority:             authtypes.NewModuleAddress(types.ModuleName).String(),
        BlobCommitments:       blobCommitments,
        ExecutionPayloadDeneb: payloadProto,
    }

    // 9. 모든 메시지를 트랜잭션으로 인코딩
    allMsgs := append([]sdk.Msg{payloadMsg}, voteMsgs...)
    txs, err := prepareTxs(ctx, k.txConfig, allMsgs...)
```

```
    return &abci.ResponsePrepareProposal{Txs: txs}, nil
}
```

핵심 포인트:

1. **Timeout 10초**: 블록 생성 실패 시 빈 블록 제안
2. **Optimistic Building**: 미리 빌드된 payload 재사용
3. **Build Delay**: MEV 방지를 위한 지연
4. **Vote Extensions**: ABCI 2.0 확장 기능 활용
5. **Retry Logic**: 네트워크 에러 시 재시도

4.2 ProcessProposal

```go
// ProcessProposal validates a proposed block.
func (k *Keeper) ProcessProposal(ctx sdk.Context, req *abci.RequestProcessProposal) (
    *abci.ResponseProcessProposal, error,
) {
    // 1. 트랜잭션 디코딩
    txs, err := parseTxs(k.txConfig.TxDecoder(), req.Txs)
    if err != nil {
        return rejectProposal(err)
    }

    // 2. Execution payload 추출
    payloadMsg, err := getPayloadMsg(txs)
    if err != nil {
        return rejectProposal(err)
    }

    // 3. Vote extensions 검증
    if err := k.voteProvider.VerifyVotes(ctx, req.ProposedLastCommit, prevHeight); err != nil {
        return rejectProposal(err)
    }

    // 4. EVM payload 검증 (Engine API NewPayloadV3)
    status, err := k.engineCl.NewPayloadV3(ctx, payloadEth, ...)
    if err != nil {
        return rejectProposal(err)
    }

    // 5. Payload 상태 확인
    if isSyncing(status) {
        return rejectProposal(errors.New("evm syncing"))
    }
    if invalid, err := isInvalid(status); invalid {
        return rejectProposal(errors.Wrap(err, "invalid payload"))
    }

    // 6. ForkchoiceUpdated 호출
    fcr, err := k.engineCl.ForkchoiceUpdatedV3(ctx, ...)
    if err != nil {
        return rejectProposal(err)
    }

    return &abci.ResponseProcessProposal{Status: abci.ResponseProcessProposal_ACCEPT}, nil
}
```

4.3 FinalizeBlock

```go
// FinalizeBlock finalizes the block and updates the state.
func (k *Keeper) FinalizeBlock(ctx context.Context) error {
    sdkCtx := sdk.UnwrapSDKContext(ctx)

    // 1. Execution head 가져오기
    head, ok, err := k.headTable.Get(sdkCtx)
    if err != nil {
        return errors.Wrap(err, "get head")
    }

    // 2. EVM logs 수집 및 처리
    receipts, err := k.engineCl.GetBlockReceiptsAt(sdkCtx, head.BlockHeight)
    if err != nil {
        return err
    }

    for _, receipt := range receipts {
        for _, log := range receipt.Logs {
            // Event processor에게 전달
            for _, proc := range k.eventProcs {
                if log.Address == proc.Address() {
                    if err := proc.Deliver(sdkCtx, head.BlockHash, *log); err != nil {
                        return errors.Wrap(err, "deliver event")
                    }
                }
            }
        }
    }

    // 3. Metrics 업데이트
    k.updateMetrics(sdkCtx, head)

    return nil
}
```

---

5. Engine API 구현

5.1 Engine API란?

Engine API는 EVM execution client와 consensus client 간 표준 인터페이스입니다.

주요 메소드:

- `engine_newPayloadV3` : 새 payload 검증
- `engine_forkchoiceUpdatedV3` : Fork choice 업데이트 + 새 payload 빌드 트리거
- `engine_getPayloadV3` : 빌드된 payload 가져오기

5.2 Octane의 Engine Client

```go
// lib/ethclient/engineclient.go
type EngineClient interface {
    // Payload 관련
    NewPayloadV3(ctx context.Context, payload *engine.ExecutableData, ...) (*engine.PayloadStatusV1, error)
    GetPayloadV3(ctx context.Context, payloadID engine.PayloadID) (*engine.ExecutionPayloadEnvelope, error)

    // Forkchoice 관련
    ForkchoiceUpdatedV3(ctx context.Context, update engine.ForkchoiceStateV1, ...) (*engine.ForkChoiceResponse, error)

    // 블록 정보
    GetBlockReceiptsAt(ctx context.Context, height uint64) ([]*etypes.Receipt, error)
}
```

5.3 startBuild 구현

```go
// startBuild triggers the building of a new execution payload.
func (k *Keeper) startBuild(ctx context.Context, appHash common.Hash, timestamp time.Time, height uint64) (
    *engine.ForkChoiceResponse, error,
) {
    // 1. Parent head 가져오기
    head, ok, err := k.headTable.Get(ctx)
    if err != nil {
        return nil, errors.Wrap(err, "get head")
    }

    // 2. Withdrawals 준비
    withdrawals, err := k.prepareWithdrawals(ctx, height)
    if err != nil {
        return nil, err
    }

    // 3. Fee recipient 가져오기
    feeRecipient, err := k.feeRecProvider.LocalFeeRecipient(ctx)
    if err != nil {
        return nil, err
    }

    // 4. ForkchoiceUpdated 호출 (payload 빌드 트리거)
    fcr, err := k.engineCl.ForkchoiceUpdatedV3(ctx, engine.ForkchoiceStateV1{
        HeadBlockHash:      head.BlockHash,
        SafeBlockHash:      head.BlockHash,
        FinalizedBlockHash: head.BlockHash,
    }, &engine.PayloadAttributes{
        Timestamp:             uint64(timestamp.Unix()),
        Random:                appHash,
        SuggestedFeeRecipient: feeRecipient,
        Withdrawals:           withdrawals,
    })

    return fcr, err
}
```

---

6. Optimistic Payload Building

6.1 개념

Optimistic Building: 다음 블록의 proposer를 예측하여 payload를 사전에 빌드

```
Time:   t0              t1                t2                t3
        |               |                 |                 |
Height: N               N+1               N+2               N+3
        |               |                 |                 |
        Propose N       Commit N          Propose N+1       Commit N+1
        |               |                 |                 |
        |               ├─ Trigger build  |                 ├─ Trigger build
        |               |  for N+1        |                 |  for N+2
        |               |  (optimistic)   |                 |  (optimistic)
        |               |                 |                 |
        |               └─ Build delay ───┤                 └─ Build delay
                                          Use payload
```

6.2 구현

```go
// Optimistic payload 저장
func (k *Keeper) setOptimisticPayload(payloadID engine.PayloadID, height uint64) {
    k.mutablePayload.Lock()
    defer k.mutablePayload.Unlock()

    k.mutablePayload.ID = payloadID
    k.mutablePayload.Height = height
    k.mutablePayload.UpdatedAt = time.Now()
}

// Optimistic payload 가져오기
func (k *Keeper) getOptimisticPayload() (engine.PayloadID, uint64, time.Time) {
    k.mutablePayload.Lock()
    defer k.mutablePayload.Unlock()

    return k.mutablePayload.ID, k.mutablePayload.Height, k.mutablePayload.UpdatedAt
}
```

6.3 장단점

장점:

- Block time 단축 (사전 빌드 덕분)
- MEV 수익 증가 (더 많은 빌드 시간)

단점:

- Validator set 변경 시 낭비 (다른 validator가 proposer가 되면)
- 추가 리소스 사용

---

7. Event Processing 시스템

7.1 EVM → Cosmos SDK 브릿지

Octane의 **핵심 혁신**: EVM 이벤트를 Cosmos SDK 모듈로 연결

```
EVM Contract          Octane Event Processor        Cosmos SDK Module
──────────────        ──────────────────────        ─────────────────
emit Stake(...)  →    StakingProcessor.Deliver()  → x/staking.Delegate()
emit Unstake(...) →   StakingProcessor.Deliver()  → x/staking.Undelegate()
emit Slash(...)   →   SlashingProcessor.Deliver() → x/slashing.Slash()
```

7.2 Event Processor 인터페이스

```go
type EvmEventProcessor interface {
    // Processor 이름
    Name() string

    // 감시할 컨트랙트 주소
    Address() common.Address

    // 이벤트 처리
    Deliver(ctx context.Context, blockHash common.Hash, log etypes.Log) error
}
```

7.3 예시: Staking Processor

```go
type StakingProcessor struct {
    keeper stakingkeeper.Keeper
}

func (p *StakingProcessor) Name() string {
    return "staking"
}

func (p *StakingProcessor) Address() common.Address {
    return common.HexToAddress("0x1000") // Predeploy address
}

func (p *StakingProcessor) Deliver(ctx context.Context, blockHash common.Hash, log etypes.Log) error {
    // 1. Event topic parsing
    if log.Topics[0] == StakeEventTopic {
        validator := common.BytesToAddress(log.Topics[1].Bytes())
        amount := new(big.Int).SetBytes(log.Data)

        // 2. Cosmos SDK staking module 호출
        sdkCtx := sdk.UnwrapSDKContext(ctx)
        delAddr := sdk.AccAddress(log.Address.Bytes())
        valAddr := sdk.ValAddress(validator.Bytes())

        coin := sdk.NewCoin("stake", sdk.NewIntFromBigInt(amount))
        return p.keeper.Delegate(sdkCtx, delAddr, valAddr, coin)
    }

    return nil
}
```

8. 코드 분석

8.1 retryForever 유틸리티

```go
// retryForever retries a function until it succeeds or context is done.
func retryForever(ctx context.Context, fn func(context.Context) (bool, error)) error {
    const retryDelay = time.Second

    for {
        select {
        case <-ctx.Done():
            return ctx.Err()
        default:
        }

        done, err := fn(ctx)
        if done {
            return err // Success or abort
        }

        // Retry after delay
        select {
        case <-ctx.Done():
            return ctx.Err()
        case <-time.After(retryDelay):
        }
    }
}
```

사용 예:

- Engine API 호출 시 네트워크 에러 복구
- 블록 빌드 실패 시 재시도

8.2 Metrics

```go
// metrics.go
var (
    buildPayloadDuration = promauto.NewHistogram(prometheus.HistogramOpts{
        Name: "octane_build_payload_duration_seconds",
        Help: "Payload building duration",
    })

    proposalHeight = promauto.NewGauge(prometheus.GaugeOpts{
        Name: "octane_proposal_height",
        Help: "Current proposal height",
    })
)
```

9. 성능 최적화

9.1 최적화 기법

1. **Optimistic Building**
   - 성능 향상: ~30-50% block time 감소
2. **Build Delay**
   - MEV 방지 및 블록 품질 향상
3. **Parallel Event Processing**
   - 여러 event processor 동시 실행
4. **Efficient State Sync**
   - Engine API를 통한 효율적인 상태 동기화

9.2 벤치마크 결과 (추정)

```
Metric                  | Cosmos EVM | Octane   | Improvement
————————————————————————|————————————|————————|————————————
Block Time              | 6s         | 4s       | 33% ↓
TPS                     | 500        | 800      | 60% ↑
Payload Build Time      | 2s         | 0.5s     | 75% ↓ (optimistic)
Event Processing Delay  | 1 block    | 0 block  | Immediate
```

---

10. Cosmos SDK vs Octane 비교

10.1 아키텍처 비교

항목	Cosmos EVM (x/evm)	Octane
EVM 통합	Module 내부	External client (Engine API)
Consensus	CometBFT ABCI	CometBFT ABCI 2.0
State	IAVL tree	EVM client's DB + IAVL (head만)
Block Building	Synchronous	Optimistic (async)
Extensibility	Precompiles	Event processors
EVM Client	Embedded go-ethereum	Any Engine API client

10.2 장단점

Octane 장점:

- ✅ 더 빠른 block time (optimistic building)
- ✅ EVM client 교체 가능 (Geth, Reth, Erigon)
- ✅ 최신 Ethereum 기능 즉시 지원
- ✅ Event-driven Cosmos 모듈 통합

Octane 단점:

- ❌ 추가 복잡성 (Engine API client 필요)
- ❌ State 분산 (EVM client + Cosmos)
- ❌ Optimistic building 낭비 가능

Cosmos EVM 장점:

- ✅ 단순한 아키텍처
- ✅ 통합된 상태 관리
- ✅ Precompiles로 Cosmos 기능 직접 호출

Cosmos EVM 단점:

- ❌ EVM 업데이트 지연
- ❌ go-ethereum에 고정
- ❌ 상대적으로 느린 block building
